## Part I

# **Applications to Graph Covering**

## **Graph Covering**

- How may graphs of certain type it takes to cover the full graph?
- $ightharpoonup K_n$  the complete graph over [n]
- ▶ Let  $G_1, ..., G_t$  be bipartite graphs over [n] with  $\bigcup_i G_i = K_n$ . What can we say about t?
- ▶ Clearly,  $t \ge \frac{\binom{n}{2}}{(n/2)^2} \approx$  2, but can we give a better bound?

#### **Theorem 1**

Let  $G_1, \ldots, G_t$  be bipartite graphs over [n] with  $\bigcup_{i=1}^t G_i = K_n$ , then  $t \ge \log n$ .

Proof: Let  $\chi(G)$  be the chromatic number of G.

- ▶  $\chi(G_i) \leq 2$  and  $\chi(K_n) = n$ .
- $\chi(G \cup G') \leq \chi(G) \cdot \chi(G'). (?)$
- $\implies \chi(\bigcup_{i=1}^t G_i) \leq 2^t$
- $\implies t \ge \log n$

## **Proving Thm 1 using entropy**

- $G_i = (A_i, B_i, E_i)$
- $\triangleright X \leftarrow [n]$
- $Y_i = \left\{ \begin{array}{ll} 0, & X \in A_i \\ 1, & X \in B_i \end{array} \right.$
- $\blacktriangleright$  X is determined by  $Y_1, \ldots, Y_t$  (?)

$$0 = H(X|Y_1, ..., Y_t) = H(X, Y_1, ..., Y_t) - H(Y_1, ..., Y_t)$$

$$\geq H(X) - \sum_i H(Y_i)$$

$$\geq \log n - t.$$

#### **Extensions**

▶ nonls(G) — non-isolated vertices in G.

#### **Theorem 2**

Let  $G_1, \ldots, G_t$  be bipartite graphs over [n] with  $\bigcup_{i=1}^t G_i = K_n$ , then  $\frac{1}{n} \sum_{i=1}^t |\mathsf{nonls}(G_i)| \ge \log n$ .

## **Definition 3 (graph content)**

Let G be a graph over [n], let  $Z \leftarrow \operatorname{nonls}(G)$  and let  $\hat{\chi}$  be a (valid) coloring of G such that  $H(\hat{\chi}(Z))$  is minimal. Then  $\operatorname{content}(G) := \frac{|\operatorname{nonls}(G)|}{n} \cdot H(\hat{\chi}(Z))$ .

#### **Theorem 4**

Let  $G_1, \ldots, G_t$  be graphs over [n] with  $\bigcup_{i=1}^t G_i = K_n$ . Then  $\sum \operatorname{content}(G_i) \ge \log n$ .

► Since content(G)  $\leq \frac{|\text{nonls}(G)|}{n}$  for bipartite G, Thm 4 yields Thm 2.

## **Proving Thm 4**

- Let  $\chi_i$  be a (valid) coloring of  $G_i$ .
- ► Let  $X \leftarrow [n]$ , and let  $Y_i = \begin{cases} \chi_i(X) & X \in \mathsf{nonls}(G_i) \\ \chi_i(Z_i) & \mathsf{otherwise}, \, \mathsf{for} \, Z_i \leftarrow \mathsf{nonls}(G_i) \, (\mathsf{ind. of the other } Z'\mathsf{s}). \end{cases}$
- $\blacktriangleright$  X is determined by  $Y_1, \ldots, Y_t$  (?)

$$0 = H(X|Y_1, ..., Y_t) = H(X, Y_1, ..., Y_t) - H(Y_1, ..., Y_t)$$

$$\geq H(X) + H(Y_1, ..., Y_t|X) - \sum_i H(Y_i)$$

$$\geq \log n + H(Y_1, ..., Y_t|X) - \sum_i H(Y_i).$$

- ▶  $Y_1, ..., Y_t$  are independent conditioned on X  $Pr[Y_1 = y_1 \land Y_2 = y_2 \mid X = z] = Pr[Y_1 = y_1 \mid X = z] \cdot Pr[Y_2 = y_2 \mid X = z]$
- ► Hence,  $H(Y_1, ..., Y_t | X) = \sum_i H(Y_i | X)$  (board)
- ▶ We conclude that  $\sum_i H(Y_i) \sum_i H(Y_i|X) \ge \log n$
- ► Since  $H(Y_i) = H(\chi_i(Z_i))$  and  $H(Y_i|X) = (1 \frac{|\text{nonls}(G_i)|}{n}) \cdot H(\chi_i(Z_i))$ , it follows that  $\sum_i H(\chi_i(Z_i)) \frac{|\text{nonls}(G_i)|}{n} \ge \log n$ .  $\square$

#### **Extension**

Let  $\alpha(G)$  be the size of the maximal independent set in G.

#### **Theorem 5**

Let 
$$G, G_1, \ldots, G_t$$
 be graphs over  $[n]$  with  $\bigcup_{i=1}^t G_i = G$ , then  $\sum \operatorname{content}(G_i) \ge \log \frac{n}{\alpha(G)}$ .

Proof: ?

## **Scrambling permutations**

#### **Theorem 6**

Let  $\mathcal S$  be a set of permutations over [n] s.t. for any triplet (i,j,k) of distinct elements of [n], exists  $\pi \in \mathcal S$  with  $\pi(i) < \pi(j) < \pi(k)$  or  $\pi(i) > \pi(j) > \pi(k)$ . Then  $|\mathcal S| \geq \frac{2}{\log e} \log n$ .

- ▶ For  $\pi \in \mathcal{S}$ , the graph  $G_{\pi} = (V, E_{\pi})$  is defined by:
  - ►  $V = \{(i,j) \in [n]^2 : i \neq j\}$
  - $E_{\pi} = \{((i,j),(k,j)) \in V^2 : \pi(i) < \pi(j) < \pi(k) \lor \pi(i) > \pi(j) > \pi(k)\}$
- ▶  $G = \bigcup_{\pi \in S} G_{\pi}$  has n connected components, each consists of (n-1)-vertex cliques:  $\{(i,j): i \in [n] \setminus \{j\}\}$  for each  $j \in [n]$ .
- $G_{\pi}$  consists of *n* complete bipartite graphs (two are empty):

$$\{(i,j) \colon \pi(i) \le \pi(j)\}\$$
and  $\{(i,j) \colon \pi(i) > \pi(j)\}\$ for each  $j \in [n]$ .

The sum of content of these bipartite graphs is

$$\textstyle \sum_{i=0}^{n-1} \, h(\frac{i}{n-1}) = (n-1) \sum_{i=0}^{n-1} \, h(\frac{i}{n-1}) \cdot \frac{1}{n-1} \leq (n-1) \int_0^1 \, h(p) dp = (n-1) \cdot \frac{\log e}{2}.$$

- ▶ By Thm 5 (applied for each component)  $|S| \cdot \frac{\log e}{2} \cdot (n-1) \ge n \log(n-1)$ .
- ► Hence,  $|S| \ge \frac{2}{\log e} \cdot \frac{n}{n-1} \cdot \log(n-1) \ge \frac{2}{\log e} \log n$ .  $\square$

## Part II

## **Differential Entropy**

## **Entropy of continues random variable**

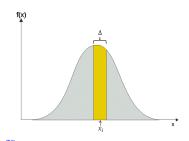

- ▶ Entropy of discrete random variable:  $H(X) = -\sum_i p_i \log p_i$
- ▶ Also used when X has infinite # of states (entropy might be infinite (?))
- ▶ Continues random variable is defined by its density function:  $f: \mathbb{R} \mapsto \mathbb{R}^+$  and  $\int_{\mathbb{R}} f(x) dx = 1$ .
- $ightharpoonup F_X(x) := \Pr[X \le x] = \int_{-\infty}^x f(x) dx$
- ► E  $X = \int x \cdot f(x) dx$  and  $\forall X = \int x^2 \cdot f(x) dx (E X)^2$
- ▶ Examples:  $X \sim [0, 1], X \sim N(0, 1)$
- H(X) must be infinite! it takes infinite number of bits to describe X
- ▶ The differential entropy of *X* is defined by  $h(X) = -\int f(x) \log f(x) dx$ .
- ▶ We focus on cases where h(X) is well defined.
- ▶ Since h is a function of the density function, we sometimes write h(f)
- ▶ If not stated otherwise, we integrate over ℝ

#### Intuition for definition of h

▶ Let  $X^{\triangle}$  be rounding of X for precision  $\triangle$ :

$$X^{\Delta} \sim (\dots, p_{-2}, p_{-1}, p_0, p_1, p_2, \dots),$$
  
where  $p_i = \int_{i \cdot \Delta}^{(i+1) \cdot \Delta} f(x) dx = f(x_i) \cdot \Delta$   
for some  $x_i \in [i \cdot \Delta, (i+1) \cdot \Delta]$  (?)

$$\blacktriangleright H(X^{\Delta}) = -\sum_{i=-\infty}^{\infty} p_i \log p_i$$

$$H(X^{\Delta}) = -\sum_{i=-\infty}^{\infty} f(x_i) \cdot \Delta \cdot \log(f(x_i) \cdot \Delta) = -\sum_{i=-\infty}^{\infty} f(x_i) \cdot \Delta \cdot (\log f(x_i) + \log \Delta)$$

$$= -\sum_{i=-\infty}^{\infty} f(x_i) \cdot \log f(x_i) \cdot \Delta - \left(\sum_{i=-\infty}^{\infty} f(x_i) \cdot \Delta\right) \log \Delta$$

- $Iim_{\Delta \to 0} H(X^{\Delta}) = h(X) \log \Delta$
- ▶ Hence,  $\lim_{\Delta \to 0} H(X^{\Delta}) + \log \Delta = h(x)$
- ▶ Intuitively, h(X) is the entropy of X plus const  $(-\log \Delta)$ .
- ▶ Note that  $\lim_{\Delta \to 0} \log \Delta = \infty$

## Properties of the entropy function

- ► Shift invariant: h(f) = h(g) for g(x) = f(x + a)
- ▶  $h(X) = -\int f(x) \log f(x) dx$  might be infinite
- $\blacktriangleright h(X)$  might be negative
- ► Example:  $X \sim [0, a] f(x) = \frac{1}{a}$  on [1, a]

$$-\int f(x) \log f(x) dx = -\log \frac{1}{a} = \log a$$
. Negative for  $a < 1$ .

- $\blacktriangleright$  h(X) should be interpreted as the uncertainty up to a certain constant
- Used for comparing two distributions

## **Common distribution (in nature)**

- ► The uniform distribution: X ~ [a, b]
- Normal (Gaussian) distribution: (we focus on E = 0 and V = 1)

$$X \sim N(0,1)$$
:  $f(x) = \frac{1}{\sqrt{2\pi}} \cdot e^{-x^2/2}$ 

► Boltzmann (Gibbs) distribution:

$$X \in \{E_1, E_2, \dots, E_m\}$$
,  $\Pr[X = E_i] = C \cdot e^{-\beta E_i}$  for  $\beta > 0$  (the distribution constant) and  $C = 1/\sum_i e^{-\beta E_i}$ .

- ▶ Describes a (discrete) physical system that can take states  $\{1, ..., m\}$  with energies  $E_1, ..., E_m$ .
- Probability is inverse to the energy
- Why are these distributions so common?
- What is common to these distributions?

## **Historical background**

- ► Shannon (1948)  $H = -\sum_i p_i \log p_i$
- But the notion of entropy already existed in statistical physics
- There, entropy energy that cannot used, statistical disorder
- ► Clausius (1865), who coined the name *entropy*, based on Carnot (1824),  $H = \int_{t} \frac{\delta Q}{T} dt$  (Q is *heat* and T is *temperature*)
- ▶ Boltzmann (1877)  $H = k \log S$  for S being the number of states a system can be in (after measuring the macro parameters: pressure, temperature)
- ▶ log #states is Shannon entropy of the uniform distribution
- Shannon looked for a name for his measure, von Neumann pointed out the relation to physics and suggested the name entropy.
- ➤ Today it is accepted that Shannon's entropy is the right notion also in statistical mechanic. Measures the uncertainty of a system energy that cannot be used.
- Carnot was also an engineer...

## Second law of thermodynamics

- The entropy of a closed physical system never decreases.
- If we wait enough time, the system tends to be in maximal entropy.
- If there are constrains, the it tends to be in maximal entropy under this constrains.
- This suggests that distributions that are common in nature, are distributions of maximal entropy, under some constrains.
- In contradiction with "reversible laws"

#### The normal distribution

- $X \sim N(0,1)$ :  $f(x) = \frac{1}{\sqrt{2\pi}} \cdot e^{-x^2/2}$
- Why is it so common?
- Answer: the central limit theorem (CLT):

Let 
$$X_1, \ldots, X_n$$
 be iid with  $\mathsf{E}\, X_i = 0$  and  $\mathsf{V}\, X_i = 1$ . Then  $\lim_{n \to \infty} \frac{\sum_i X_i}{\sqrt{n}} = N(0,1)$ .

- ▶ But why does it converge to N(0,1)??
- CLT holds also in many other variants: not id, not fully independent, ...
- ▶ We know that  $\mathsf{E} \, \frac{\sum_i X_i}{\sqrt{n}} = \mathsf{0}$  and  $\mathsf{V} \, \frac{\sum_i X_i}{\sqrt{n}} = \mathsf{1}$ , but it could have converge to any other distribution with these constraints.
- ► The reason is that N(0,1) has the highest entropy among all distribution with E=0 and V=1.
- ► CLT and the normal distribution where known and studied way before Shannon, yet this striking property was not known until his theory.

## The normal distribution, cont.

#### **Theorem 7**

$$h(X) \le h(N(0,1))$$
, for any rv X with  $\forall X = 1$ .

- Among the distributions of V = 1, the distribution N(0, 1) has maximal entropy.
- Generalizes to any variance:

$$h(X) \leq h(N(0,V(X))) = \frac{1}{2} \cdot \log(2\pi e) \cdot V(X)$$

Let g be a density function with  $\int g(x)x^2dx = 1$ , and let  $f(x) = \frac{1}{\sqrt{2\pi}} \cdot e^{-x^2/2}$ . We will show that

- 1.  $-\int g(x) \log g(x) dx \le -\int g(x) \log f(x) dx$
- 2.  $-\int g(x) \log f(x) dx = -\int f(x) \log f(x)$

$$-\int g(x)\log g(x)dx \le -\int g(x)\log f(x)dx$$

#### Claim 8

 $-\int g(x) \log g(x) dx \le -\int g(x) \log q(x) dx$  for any two density functions q, g.

Proof: (the continuous version of Q1 in handout 1)

- ▶ Jensen: For any function t and density function  $\lambda$ :  $\int \lambda(x) \log t(x) \le \log \int \lambda(x) t(x) dx$
- Assume for simplicity that g(x) > 0 for all x.
- ▶ By Jensen,  $\int g(x) \log \frac{q(x)}{g(x)} \le \log \int g(x) \frac{q(x)}{g(x)} dx = \log 1 = 0$
- ► Hence,  $-\int g(x) \log g(x) \le -\int g(x) \log q(x)$

$$-\int g(x)\log f(x)dx = -\int f(x)\log f(x)dx$$

#### Claim 9

Exists  $c \in \mathbb{R}$  such that  $-\int g(x) \log f(x) dx = c$  for any density function g with  $\int g(x)x^2 dx = 1$ .

Hence,  $-\int g(x) \log f(x) dx = -\int f(x) \log f(x) dx$ .

Proof:  

$$-\int g(x)\log f(x)dx = -\int g(x)\log \frac{1}{\sqrt{2\pi}} \cdot e^{-x^2/2}dx$$

$$= -\int g(x)\left(\log \frac{1}{\sqrt{2\pi}} - \frac{x^2}{2} \cdot \log e\right)$$

$$= -\log \frac{1}{\sqrt{2\pi}} \int g(x)dx + \frac{\log e}{2} \int g(x)x^2dx$$

$$= -\log \frac{1}{\sqrt{2\pi}} + \frac{\log e}{2}.$$

## The Boltzmann distribution

- ▶ States  $\{1, ..., m\}$ , energies  $E_1, ..., E_m$ .
- ▶  $\Pr[X = E_i] = C \cdot e^{-\beta E_i} \text{ for } \beta > 0 \text{ and } C = 1/\sum_i e^{-\beta \cdot E_i}$
- We will denote it by  $\sim B(\beta, E_1, \dots, E_m)$
- Like the exponential distribution (i.e.,  $f(x) = \lambda e^{-\lambda x}$ ), but discrete.
  - ▶ Describes a (discrete) physical system that can take states  $\{1, ..., m\}$  with energies  $E_1, ..., E_m$ .
  - Probability is inverse to energy

#### **Theorem 10**

Let  $X \sim B(\beta, E_1, \dots, E_m)$ . Then  $H(Y) \leq H(X)$  for any rv Y over  $\{E_1, \dots, E_m\}$ , with E Y = E X.

► The Boltzmann distribution is maximal among all distributions of the same energy.

## **Proving Theorem 10**

- ▶ Let  $X \sim (p_1, \ldots, p_m)$  and  $Y \sim (q_1, \ldots, q_m)$ .
- ►  $H(Y) \le \sum_i q_i \log p_i$  (Q1 in Handout 1)
- ▶ Let  $C = 1/\sum_i e^{-\beta \cdot E_i}$ .

Then

$$\sum_{i} q_{i} \log p_{i} = \sum_{i} q_{i} \log(C \cdot e^{-\beta E_{i}})$$

$$= \sum_{i} q_{i} \log C - \sum_{i} q_{i} \cdot \beta E_{i} \cdot \log e$$

$$= \log C - \beta \cdot \log e \cdot \sum_{i} q_{i} E_{i}$$

$$= \log C - \beta \cdot \log e \cdot E X$$

▶ Hence,  $\sum_i q_i \log p_i = \sum_i p_i \log p_i$ .  $\square$ 

## The uniform distribution

- $\blacktriangleright$   $X \sim [a, b].$
- ► E  $X = \frac{1}{2}(a+b)$  and  $V X = \frac{1}{12}(b-a)^2$
- ▶ What come to mind when saying "X takes values in [0, 1]".

#### Theorem 11

$$h(X) \le -h(\sim [a,b])$$
, for any RV with Supp $(X) \subseteq [a,b]$ .

Proof: ?

## Differential entropy bound on discrete entropy

### **Proposition 12**

Let 
$$X \sim (p_1, p_2, ...)$$
, then  $H(X) \leq \frac{\log 2\pi e}{2} \cdot \left(\sum_{i=1}^{\infty} p_i i^2 - \left(\sum_{i=1}^{\infty} p_i i\right)^2 - \frac{1}{12}\right)$ 

We assume wlg. that  $p_i = \Pr[X = i]$ .

▶ Let  $U \sim [0, 1]$ , let  $\tilde{X} = X + U$  and let  $f_{\tilde{X}}$  be the density function of  $\tilde{X}$ .

$$H(X) = -\sum_{i=1}^{\infty} p_i \log p_i$$

$$= -\sum_{i=1}^{\infty} \left( \int_i^{i+1} f_{\tilde{X}}(x) dx \right) \cdot \log p_i = -\sum_{i=1}^{\infty} \int_i^{i+1} f_{\tilde{X}}(x) \log p_i dx$$

$$= -\sum_{i=1}^{\infty} \int_i^{i+1} f_{\tilde{X}}(x) \log f_{\tilde{X}}(x) dx \qquad (f_{\tilde{X}}(x) = p_i \text{ for all } x \in [i, i+1])$$

$$= -\int_1^{\infty} f_{\tilde{X}}(x) \log f_{\tilde{X}}(x) dx$$

$$= h(\tilde{X})$$

## Differential entropy bound on discrete entropy, cont.

Hence,

$$H(X) = h(\tilde{X})$$

$$\leq \frac{1}{2} \log(2\pi e) V(\tilde{X})$$

$$= \frac{1}{2} \log(2\pi e) (V(X) + V(U))$$

$$= \frac{\log 2\pi e}{2} \cdot \left( \left( \sum_{i=1}^{\infty} p_i i^2 - (\sum_{i=1}^{\infty} p_i i)^2 \right) + \frac{1}{12} \right)$$

- ► How good is this bound?
- ▶ Let  $X \sim (\frac{1}{2}, \frac{1}{2})$ . Hence,  $V[X] = \frac{1}{4}$  and H(X) = 1.
- ▶ Proposition 12 grantees that  $H(X) \le \frac{\log 2\pi e}{2} (\frac{1}{4} + \frac{1}{12}) \sim 1.255$
