Tel Aviv University.

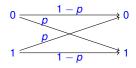

November 17, 2015

# Part I

# **Channel Capacity**

# The problem

- ▶ We want to send a message  $\mathbf{x} = (x_1, ..., x_m) \in \{0, 1\}^m$ , but the communication channel is faulty
- ► Each bit is (independently) flipped w.p. p (e.g., 0.1)

- (expected) Error rate is p
- Such "channel" is called Binary Symmetric Channel (BSC)
- ▶ When sending m bits, we have  $\approx pm$  errors
- Can we send bits with smaller error?

#### **Solution**

- Obvious solution is "error correction codes (ECC)"
- Most simple example: send each bit three times, and take majority
- Error happens if the channel errs at least twice
- For p = 0.1: happens w.p.  $3p^2(1-p) + p^3 = 3 \cdot 0.01 \cdot 0.9 + 0.001 = 0.028$
- Error rate: .028
- Transmission rate: 1/3 (i.e., # of bits recovered / #of bits transmitted)
- We reduced the error rate by reducing the transmission rate.
- Can we reduce the error rate, without reducing the transmitting rate too much?
- Before Shannon it was believed that very small error rate requires very small transmission rate.

#### Shannon's result

- Shannon showed that you can reduce the error rate towards 0, without reducing the transmission rate towards 0
- For any c < C<sub>p</sub>, exists a code with transmission rate c that is correct w.h.p.
- ► Example: for p = .1,  $C_p > \frac{1}{2}$ . Hence, for sending  $\mathbf{x} = (x_1, ..., x_m)$ , one can send 2m bits, such that  $\mathbf{x}$  is recovered w.p. close to 1
- ▶ More generally,  $\forall p \in [0,1] \ \exists C_p$  such that for sending  $\mathbf{x} \in \{0,1\}^m$ , one can send  $\approx \frac{m}{C_p}$  bits, and  $\mathbf{x}$  is recovered w.p. close to 1
- $C_p$  might be 0 (i.e., for  $p = \frac{1}{2}$ )
- A revolution in EE and the whole world

#### **Error correction code**

- ► Message to send  $\mathbf{x} = (x_1, ..., x_m) \in \{0, 1\}^m$
- ► Encoding scheme:  $f: \{0,1\}^m \mapsto \{0,1\}^n$  (n > m)
- ▶ Decoding scheme:  $g: \{0,1\}^n \mapsto \{0,1\}^m$
- $ightharpoonup \frac{m}{n}$  transmission rate
- ▶ Sender sends f(x) rather than x
- Receiver decodes the message by applying g

$$\underbrace{\mathbf{x}}_{m \text{ bits}} \xrightarrow{\text{encoding}} \underbrace{f(\mathbf{x})}_{n \text{ bits}} \xrightarrow{\text{channel}} \underbrace{f(\mathbf{x}) \oplus Z}_{\text{bitwise XOR}} \xrightarrow{\text{decoding}} g(f(\mathbf{x}) \oplus Z)$$

$$Z = (Z_1, \dots, Z_n) \text{ where } Z_1, \dots, Z_n \text{ iid } \sim (1 - p, p) \text{ (i.e., over } \{0, 1\} \text{ with } Pr[Z_i = 1] = p)$$

- ▶ We hope  $g(f(\mathbf{x}) \oplus Z) = \mathbf{x}$
- ► ECCs are everywhere
- ECC Vs compression

#### Shannon's theorem

#### **Theorem 1**

$$\forall p \quad \exists C_p, \text{ s.t. } \forall \varepsilon > 0 \quad \exists m_{\varepsilon}, \text{ s.t. } \forall m > m_{\varepsilon} \text{ and } n > m(\frac{1}{C_p} + \varepsilon),$$

$$\exists f \colon \{0,1\}^m \mapsto \{0,1\}^n \text{ and } g \colon \{0,1\}^n \mapsto \{0,1\}^m, \text{ s.t. } \forall \mathbf{x} \in \{0,1\}^m \colon$$

$$\Pr_{z \leftarrow Z = (Z_1, \dots, Z_n)} [g(f(\mathbf{x}) \oplus z) \neq \mathbf{x}] \leq \varepsilon$$

for 
$$Z_1, \ldots, Z_n$$
 iid  $\sim (1 - p, p)$ .

- ►  $C_p = 1 h(p)$  the channel capacity  $p = .1 \implies C_p = 0.5310 > \frac{1}{2}$   $p = .25 \implies C_p \approx \frac{1}{5}$
- Tight theorem
- ▶ We prove a weaker variant that holds w.h.p. over  $\mathbf{x} \leftarrow \{0,1\}^m$

# **Hamming distance**

- ► For  $\mathbf{y} = (y_1, ..., y_n) \in \{0, 1\}^n$ , let  $\|\mathbf{y}\|_1 = \sum_i y_i$  Hamming weight of  $\mathbf{y}$
- ▶  $\|\mathbf{y} \mathbf{y}'\|_1 = \|\mathbf{y} \oplus \mathbf{y}'\|_1$  Hamming distance of  $\mathbf{y}$  from  $\mathbf{y}'$ ; # of places differ.

# Proving the theorem

- Fix  $p \in [0, \frac{1}{2})$  and  $\varepsilon > 0$ , and let  $m > m_{\varepsilon}$  and  $n \ge m(\frac{1}{C_p} + \varepsilon)$ , for  $m_{\varepsilon}$  to be determined by the analysis. (Recall  $C_p = 1 h(p)$ ).
- ▶ We show  $\exists f : \{0,1\}^m \mapsto \{0,1\}^n \text{ and } g : \{0,1\}^n \mapsto \{0,1\}^m, \text{ s.t. } \Pr_{\mathbf{x} \leftarrow \{0,1\}^m} [g(f(\mathbf{x}) \oplus Z) \neq \mathbf{x}] \leq \varepsilon$
- g(y) returns  $\operatorname{argmin}_{\mathbf{x}' \in \{0,1\}^m} |y f(\mathbf{x}')|$
- ▶ So it all boils down to finding *f* s.t.

$$\Pr_{\mathbf{x} \leftarrow \{0,1\}^m; y = f(\mathbf{x}) \oplus Z} \left[ \forall \mathbf{x}' \in \{0,1\}^m \setminus \{\mathbf{x}\} \colon |f(\mathbf{x}) - y| < |f(\mathbf{x}') - y| \right] \ge 1 - \varepsilon$$

- Idea: for p' > p to be determined later, find f s.t. w.h.p. over x and Z:
  - (1)  $|f(\mathbf{x}) \oplus Z, f(\mathbf{x})| \leq p'n$
  - (2)  $|f(\mathbf{x}) \oplus Z, f(\mathbf{x}')| > p'n$  for all  $\mathbf{x}' \neq \mathbf{x}$

- ▶ We choose *f* uniformly at random (what does it mean?)
- Non-constructive proof
- Probabilistic method

# Proving there exists good f

- Fix p' > p such that  $\frac{1}{C_{p'}} \frac{1}{C_p} \le \frac{\varepsilon}{2}$
- ► For  $y \in \{0,1\}^n$ , let  $B_{p'}(y) = \{y \in \{0,1\}^n : \|y' y\|_1 \le p'n\}$
- (1) By weak low of large numbers,  $\exists n' \in \mathbb{N} \text{ s.t. } \forall n \geq n' \text{ and } \forall \mathbf{x} \in \{0, 1\}^m$ :  $\alpha_n := \Pr_{z \leftarrow Z} [(f(\mathbf{x}) \oplus z) \notin B_{p'}(f(\mathbf{x}))] \leq \frac{\varepsilon}{2}$  (for any fixed f)
  - ► Fact (proved later):  $b(p') = |B_{p'}(y)| \le 2^{n \cdot h(p')}$

$$\Rightarrow \forall \mathbf{x} \neq \mathbf{x}' \in \{0,1\}^m : \Pr_f[f(\mathbf{x}) \oplus Z \in B_{p'}(f(\mathbf{x}'))] = \frac{b(p')}{2^n} \le \frac{2^{n \cdot h(p')}}{2^n} = 2^{-nC_{p'}}$$

$$\implies \forall \mathbf{x} \in \{0,1\}^m : \Pr_f \left[ \exists \mathbf{x}' \neq \mathbf{x} \in \{0,1\}^m : f(\mathbf{x}) \oplus Z \in B_{\rho'}(f(\mathbf{x}')) \right] \le 2^{m-nC_{\rho'}}$$

$$\implies \mathsf{Pr}_{\mathbf{x},f}\left[\exists \mathbf{x}' \neq \mathbf{x} \in \{0,1\}^m \colon f(\mathbf{x}) \oplus Z \in \mathcal{B}_{p'}(f(\mathbf{x}'))\right] \leq 2^{m-nC_{p'}}$$

$$\implies \exists \mathbf{f} \text{ s.t. } \beta_{m,n} := \mathsf{Pr}_{\mathbf{x}} \left[ \exists \mathbf{x}' \neq \mathbf{x} \in \{0,1\}^m \colon f(\mathbf{x}) \oplus Z \in \mathcal{B}_{p'}(f(\mathbf{x}')) \right] \leq 2^{m-nC_{p'}}$$

$$\implies \beta_{m,n} \leq \frac{\varepsilon}{2}, \text{ for } n \geq \frac{m}{C_{p'}} - \log \varepsilon + 1 = m(\frac{1}{C_{p'}} + \frac{1 - \log \varepsilon}{m})$$

(2) 
$$\beta_{m,n} \leq \frac{\varepsilon}{2}$$
, for  $m \geq m' = \frac{2(1 - \log \varepsilon)}{\varepsilon}$  and  $n \geq m(\frac{1}{C_p} + \frac{\varepsilon}{2} + \frac{1 - \log \varepsilon}{m}) = m(\frac{1}{C_p} + \varepsilon)$ 

► Hence, for  $m > m_{\varepsilon} = \max\{m', n'\}$  and  $n > m(\frac{1}{C_{\rho}} + \varepsilon)$ , it holds that  $\Pr_{\mathbf{x} \leftarrow \{0,1\}^m} [g(f(\mathbf{x}) \oplus Z) \neq \mathbf{x}] \leq \alpha_n + \beta_{m,n} \leq \varepsilon$ .  $\square$ 

#### **Tightness**

Let 
$$X \leftarrow \{0,1\}^m$$
,  $Z = (Z_1, ..., Z_n)$ , for  $Z_1, ..., Z_n$  iid  $\sim (1-p,p)$ , let  $f : \{0,1\}^m \mapsto \{0,1\}^n$ ,  $g : \{0,1\}^n \mapsto \{0,1\}^m$ , and let  $Y = f(X)$ .

#### **Theorem 2**

Assume 
$$\Pr[g(Y) = X] \ge 1 - \varepsilon$$
, then  $nC_p \ge m(1 - \varepsilon) - 1$ .

- ▶ Recall that Thm 1 allows  $nC_p = m(1 + \varepsilon C_p) + 1$ .
- ▶ Hence,  $\lim_{\varepsilon \to 0} \frac{m}{n} = C_p$

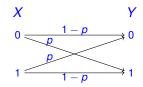

#### Proof:

$$\stackrel{\bullet}{\longrightarrow} \underbrace{X}_{n \text{ bits}} \longrightarrow \underbrace{f(X)}_{n \text{ bits}} \longrightarrow \underbrace{f(X) \oplus Z}_{Y} \longrightarrow \underbrace{g(f(X) \oplus Z)}_{g(Y)}$$

- ▶ By Fano,  $H(X|Y) \le h(\varepsilon) + \varepsilon \log(2^m 1) \le 1 + \varepsilon m$
- $I(X; Y) = H(X) H(X|Y) \ge m \varepsilon m 1 = m(1 \varepsilon) 1$
- $\vdash$  H(Y|X) = H(X,Y) H(X) = H(X,Z) H(X) = H(Z) = nh(p)
- ► I(X; Y) = H(Y) H(Y|X) = n nh(p)
- ► Hence,  $m(1 \varepsilon) \le I(X; Y) + 1 = n(1 h(p)) + 1 = nC_p + 1$

# Why $C_p = 1 - h(p)$ ?, intuitive explanation

▶ Let  $X \leftarrow \{0,1\}$ ,  $Z \sim (1-p,p)$  and  $Y = X \oplus Z$ 

- $I(X; Y) = H(Y) H(Y|X) = H(Y) H(Z) = 1 h(p) = C_p$
- ► Received bit "gives" Cp information about transmitted bit
- ► Hence, to recover m bits, we need to send at least  $m \cdot \frac{1}{C_p}$  bits

#### A different proof:

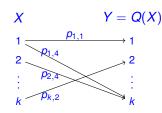

- ▶ Let  $X \leftarrow \{0,1\}^m$ , Y = f(X) and assume that g(Y) = X.
- ► Hence,  $n \ge H(Y) = H(X, Z) = m + nh(p)$
- ► Hence,  $n(1 h(p)) = nC_p \ge m$

#### **General communication channel**

 $Q: [k] \mapsto [k]$  that channel (a probabilistic function)

$$p_{i,j} = \Pr\left[Q(i) = j\right]$$

- ►  $\mathbf{x} = (x_1, \dots, x_m) \in \{0, 1\}^m$
- ► Encoding function  $f: \{0,1\}^m \mapsto \{1,\ldots,k\}^n$
- ▶ Decoding function  $g\{1,...,k\}^n \mapsto \{0,1\}^m$
- $\blacktriangleright \mathbf{x} \stackrel{\text{encoding}}{\longrightarrow} f(\mathbf{x}) \stackrel{\text{channel}}{\longrightarrow} Q(f(\mathbf{x})) \stackrel{\text{decoding}}{\longrightarrow} g(Q(f(\mathbf{x})))$
- ► We hope for  $g(Q(f(\mathbf{x}))) = \mathbf{x}$
- ▶ Channel capacity  $C_Q = \max_p C(p)$ , for  $c(p) := I(X_p; Q(X_p))$  and  $X_p \sim p$ .
- The maximal information Y gives on X
- Shannon theorem:  $\forall Q$  and  $\forall \varepsilon > 0$ ,  $\exists m_{\varepsilon} : \forall m > m_{\varepsilon}$  and  $\forall n > m(\frac{1}{C_Q} + \varepsilon) : \exists f, g$  as above s.t.  $\Pr_Q[g(Q(f(\mathbf{x}))) \neq \mathbf{x}] \leq \varepsilon$ , for all  $\mathbf{x} \in \{0, 1\}^m$ .
- ▶ Proof: similar lines to the binary case, but more subtle distribution for *f*

#### **Discussion**

- Tight result
- Non-constructive
- Coding theory: design explicit (and efficient) code achieving the same bounds
- Application: faulty communication, storage
- Combination of data compression and ECC

# Part II

# **Hamming Ball**

# Why $H(X_1, ..., X_n) \leq \sum_i H(X_i)$ so useful?

- ▶  $\log |S| = H(X) \le \sum_i (X_i)$  implies  $|S| \le 2^{\sum_i H(X_i)}$
- ▶ If  $\sum_i H(X_i)$  is small, then  $\mathcal{S}$  is small  $X_i$  are unbalanced, e.g.,  $\sim (0.1, 0.9)$ , implies  $|\mathcal{S}| \leq 2^{n \cdot h(0.1)} \leq 2^{n/2}$
- ▶ S is large implies  $\sum_i H(X_i)$  is large, hence most  $X_i$  are almost balanced
- ▶  $|S| \ge 2^n/2$  implies  $\mathsf{E}_{i \leftarrow [n]} \left[ H(X_i) \right] \ge 1 \frac{1}{n}$
- Most Xi are close to uniform

# **Hamming ball**

- ▶  $p \le \frac{1}{2}$ ;  $S = \{(a_1, ..., a_n) \in \{0, 1\}^n : \sum_i a_i \le pn\}$
- $\blacktriangleright |\mathcal{S}| = \sum_{k=0}^{\lfloor pn \rfloor} \binom{n}{k}$
- $\blacktriangleright X = (X_1, \ldots, X_n) \leftarrow S$
- ▶  $\sum_i X_i \le pn \implies E[\sum X_i] \le pn$ , and by symmetry  $E[X_i] \le p$  for every i
- ▶ Hence,  $Pr[X_i = 1] \le p$  or every *i*.
- $\implies H(X_i) \leq h(p)$  for every i
- $\implies |S| \leq 2^{\sum_i H(X_i)} \leq 2^{nh(p)}$
- $\implies \sum_{k=0}^{\lfloor pn\rfloor} \binom{n}{k} \leq 2^{nh(p)}$

# **Corollary 3**

For 
$$y \in \{0,1\}^n$$
 and  $p \in [0,\frac{1}{2}]$ , let  $B_p(y) = \{y \in \{0,1\}^n : \|y'-y\|_1 \le pn\}$ .  
Then  $|B_p(y)| = \sum_{k=0}^{\lfloor pn \rfloor} \binom{n}{k} \le 2^{n \cdot h(p)}$ 

Very useful estimation. Weaker variants follows by AEP or Stirling,

# Hamming ball, cont.

The above bound yields the following concentration bound:

### **Corollary 4**

Let  $X_1, \ldots, X_n$  be iid uniform bits and let  $p \in [0, \frac{1}{2}]$ , then  $\Pr\left[\sum_i X_i \le pn\right] = \Pr\left[(X_1, \ldots, X_n) \in \mathcal{S}\right] \le 2^{nh(p)} \cdot 2^{-n} = 2^{-n(1-h(p))}$ .

Very useful inequality. No Chernoff just IT

# Part III

# **Combinatorial Applications**

#### **Movies**

- ▶  $2^n$  people, m = 3n movies.
- Every pair of movies was seen by at least 90% of the people
- Claim: there exist two people who saw exactly the same set of movies
- ▶  $X \leftarrow [2^n]$  a random person
- $ightharpoonup Y_i = g_i(X)$
- $\forall i,j: H(Y_i,Y_j) \leq H(0.9,\frac{0.1}{3},\frac{0.1}{3},\frac{0.1}{3}) \leq \frac{2}{3}$
- ▶  $H(Y = (Y_1, ..., Y_m)) \le H(Y_1, Y_2) + H(Y_3, Y_4) + ... + H(Y_{m-1}, Y_m) < \frac{3n}{2} \cdot \frac{2}{3} = n = H(X)$
- ► Hence, X is not determined by Y

# Isoperimetric inequality

- $\triangleright$   $S \subseteq \{0,1\}^n$
- ► Edges of  $S E = \{(u, v) \in S : |u v| = 1\}$

#### **Theorem 5**

$$|E| \leq \frac{1}{2} \cdot |\mathcal{S}| \cdot \log |\mathcal{S}|$$

- ► Equality if S is "face" :  $S = \{(\mathbf{x}, \mathbf{y}) : \mathbf{y} \in \{0, 1\}^d\}$  for some  $\mathbf{x} \in \{0, 1\}^{n-d}$
- ightharpoonup Example:  $\mathcal S$  is a **face** of the 3-dimensional cube

$$n = 3$$
,  $|S| = 4$ , implies  $|E| \le \frac{1}{2} \cdot 4 \cdot \log 4 = 4$ 

- ▶  $E_i$  edges of E in direction i  $(E = \bigcup_{i \in [n]} E_i)$
- ▶  $X = (X_1, ..., X_n) \leftarrow S$  and  $X_{-i} = (X_1, X_2, ..., X_{i-1}, X_{i+1}, ..., X_n)$

#### Lemma 6

$$H(X_i|X_{-i}) = \frac{2|E_i|}{|S|}$$

#### Proving Thm 5:

$$\log |\mathcal{S}| \ge H(X_1, \dots, X_n) = H(X_1) + H(X_2|X_1) + \dots + H(X_n|X_1, X_2, \dots, X_{n-1})$$

$$\ge H(X_1|X_{-1}) + H(X_2|X_{-2}) + \dots + H(X_n|X_{-n}) = \sum_{i \in I} \frac{2|E_i|}{|S_i|} = \frac{2|E|}{|S_i|}. \quad \Box$$

# **Proving Lemma 6**

We prove for i = 1

- ▶  $E = \{(u, v) \in S : |u v| = 1\}$  and  $E_1$  contains edges of E in direction 1
- ▶  $S_{-1} = \{ \mathbf{y} \in \{0, 1\}^{n-1} : \exists x \in \{0, 1\} \text{ s.t. } (x, \mathbf{y}) \in S \}.$  (S projected on (2, ..., n))
- $\qquad \qquad \bullet \ \, \mathcal{S}^e_{-1} = \{ \textbf{y} \in \{0,1\}^{n-1} \colon (0,\textbf{y}), (1,\textbf{y}) \in \mathcal{S} \} \text{ and } \mathcal{S}^{\neg e}_{-1} = \mathcal{S}_{-1} \setminus \mathcal{S}^e_{-1} \\$
- $\blacktriangleright |\mathcal{S}| = 2 \left| \mathcal{S}_{-1}^{e} \right| + \left| \mathcal{S}_{-1}^{\neg e} \right|$
- ightharpoonup  $|E_1| = |S_{-1}^e|$
- ►  $H(X|X_{-1}) = \text{Pr}\left[X_{-1} \in \mathcal{S}_{-1}^{e}\right] \cdot 1 = \frac{2|\mathcal{S}_{-1}^{e}|}{2|\mathcal{S}_{-1}^{e}| + |\mathcal{S}_{-1}^{-e}|} = \frac{2|\mathcal{E}_{1}|}{|\mathcal{S}|}$
- **.** . . .
