Part I

Joint and Conditional Entropy

Joint entropy

▶ Recall that the entropy of rv X, is defined by

$$H(X) = -\sum_{x \in \mathcal{X}} \mathsf{P}_X(x) \log \mathsf{P}_X(x)$$

▶ Shorter notation: for $X \sim p$, let $H(X) = -\sum_x p(x) \log p(x)$
(where the summation is over the domain of X).

▶ The joint entropy of (jointly distributed) rvs X and Y with $(X, Y) \sim p$, is

$$H(X, Y) = -\sum_{x,y} p(x, y) \log p(x, y)$$

This is simply the entropy of the rv $Z = (X, Y)$.

▶ Example:

X\\$^Y$	0	1
0	$\frac{1}{4}$	$\frac{1}{4}$
1	$\frac{1}{2}$	0

$$\begin{aligned}
H(X, Y) &= -\frac{1}{2} \log \frac{1}{\frac{1}{2}} - \frac{1}{4} \log \frac{1}{\frac{1}{4}} - \frac{1}{4} \log \frac{1}{\frac{1}{4}} \\
&= \frac{1}{2} \cdot 1 + \frac{1}{2} \cdot 2 = 1\frac{1}{2}
\end{aligned}$$

Joint entropy, cont.

▶ The joint entropy of $(X_1, \ldots, X_n) \sim p$, is

$$H(X_1, \ldots, X_n) = - \sum_{x_1, \ldots, x_n} p(x_1, \ldots, x_n) \log p(x_1, \ldots, x_n)$$

Conditional entropy

► Let $(X, Y) \sim p$, let $p_X = \sum_y p(x, y)$, $p_Y = \sum_x p(x, y)$ and $p_{Y|X}(y|x) = \frac{p(x,y)}{p_Y(y)}$.

► For $x \in \text{Supp}(X)$, the random variable $Y|_{X=x}$ is well defined (distributed according to $q(y) = p_{Y|X}(y|x)$).

► The entropy of Y conditioned on X, is defined by

$$H(Y|X) := \underset{x \leftarrow X}{\mathsf{E}} H(Y|_{X=x})$$

► Measures the uncertainty in Y given X.

►
$$
\begin{aligned}
H(Y|X) &= \sum_{x \in \mathcal{X}} p_X(x) \cdot H(Y|_{X=x}) \\
&= - \sum_{x \in \mathcal{X}} p_X(x) \sum_{y \in \mathcal{Y}} p_{Y|X}(y|x) \log p_{Y|X}(y|x) \\
&= - \sum_{x \in \mathcal{X}, y \in \mathcal{Y}} p(x, y) \log p_{Y|X}(y|x) \\
&= - \underset{(X,Y)}{\mathsf{E}} \log p_{Y|X}(Y|X) = - \underset{Z = p_{Y|X}(Y|X)}{\mathsf{E}} \log Z
\end{aligned}
$$

Conditional entropy, cont.

▶ Example

$_X\diagdown^Y$	0	1
0	$\frac{1}{4}$	$\frac{1}{4}$
1	$\frac{1}{2}$	0

What is $H(Y|X)$ and $H(X|Y)$?

$$\begin{aligned}
H(Y|X) &= \underset{x \leftarrow X}{\mathsf{E}} H(Y|_{X=x}) \\
&= \frac{1}{2} H(Y|_{X=0}) + \frac{1}{2} H(Y|_{X=1}) \\
&= \frac{1}{2} H(\frac{1}{2}, \frac{1}{2}) + \frac{1}{2} H(1, 0) = \frac{1}{2}.
\end{aligned}$$

$$\begin{aligned}
H(X|Y) &= \underset{y \leftarrow Y}{\mathsf{E}} H(X|_{Y=y}) \\
&= \frac{3}{4} H(X|_{Y=0}) + \frac{1}{4} H(X|_{Y=1}) \\
&= \frac{3}{4} H(\frac{1}{3}, \frac{2}{3}) + \frac{1}{4} H(1, 0) = 0.6887 \neq H(Y|X).
\end{aligned}$$

Conditional entropy, cont..

▶

$$H(X|Y,Z) = \mathop{E}_{(y,z)\leftarrow(Y,Z)} H(X|_{Y=y,Z=z})$$
$$= \mathop{E}_{y\leftarrow Y} \mathop{E}_{z\leftarrow Z|_{Y=y}} H(X|_{Y=y,Z=z})$$
$$= \mathop{E}_{y\leftarrow Y} \mathop{E}_{z\leftarrow Z|_{Y=y}} H((X|_{Y=y})|_{Z=z})$$

Let $(X_y, Z_y) = (X, Z)|_{Y=y}$. Then

$$H(X|Y,Z) = \mathop{E}_{y\leftarrow Y} \mathop{E}_{z\leftarrow Z_y} H(X_y|_{Z=z})$$
$$= \mathop{E}_{y\leftarrow Y} \mathop{E}_{z\leftarrow Z_y} H(X_y|_{z_y=z})$$
$$= \mathop{E}_{y\leftarrow Y} H(X_y|Z_y)$$

Relating mutual entropy to conditional entropy

- What is the relation between $H(X)$, $H(Y)$, $H(X, Y)$ and $H(Y|X)$?

- Intuitively, $0 \leq H(Y|X) \leq H(Y)$

  Non-negativity is immediate. We prove upperbound later.

- We will also see that $H(Y|X) = H(Y)$ iff X and Y are independent.

- In our example, $H(Y) = H(\frac{3}{4}, \frac{1}{4}) > \frac{1}{2} = H(Y|X)$

- Note that $H(Y|_{X=x})$ might be larger than $H(Y)$ for some $x \in \text{Supp}(X)$.

- Chain rule (proved next). $H(X, Y) = H(X) + H(Y|X)$

- Intuitively, uncertainty in (X, Y) is the uncertainty in X plus the uncertainty in Y given X.

- $H(Y|X) = H(X, Y) - H(X)$ is as an alternative definition for $H(Y|X)$.

Chain rule (for the entropy function)

Claim 1

For rvs X, Y, it holds that $H(X, Y) = H(X) + H(Y|X)$.

▶ Proof immediately follow by the grouping axiom:

X^Y			
	$P_{1,1}$	...	$P_{1,n}$
	$\vdots$	$\vdots$	$\vdots$
	$P_{n,1}$	...	$P_{n,n}$

Let $q_i = \sum_{j=1}^n p_{i,j}$ $(= \Pr[X = i]$

$$H(P_{1,1}, \ldots, P_{n,n})$$
$$= H(q_1, \ldots, q_n) + \sum_i q_i H(\frac{P_{i,1}}{q_i}, \ldots, \frac{P_{i,n}}{q_i})$$
$$= H(X) + H(Y|X).$$

▶ Another proof. Let $(X, Y) \sim p$, and recall that $p(x, y) = p_X(x) \cdot p_{Y|X}(y|x)$.

$\implies \log p(x, y) = \log p_X(x) + \log p_{Y|X}(y|x)$

$\implies \operatorname{E} \log p(X, Y) = \operatorname{E} \log p_X(X) + \operatorname{E} \log p_{Y|X}(Y|X)$

$\implies H(X, Y) = H(X) + H(Y|X).$

$H(Y|X) \leq H(Y)$

Jensen inequality: for any concave function f, values $t_1, \ldots, t_k$ and $\lambda_1, \ldots, \lambda_k \in [0,1]$ with $\sum_i \lambda_i = 1$, it holds that $\sum_i \lambda_i f(t_i) \leq f(\sum_i \lambda_i t_i)$.
Let $(X, Y) \sim p$.

$$
\begin{aligned}
H(Y|X) &= -\sum_{x,y} p(x,y) \log p_{Y|X}(y|x) \\
&= \sum_{x,y} p(x,y) \log \frac{p_X(x)}{p(x,y)} \\
&= \sum_{x,y} p_Y(y) \cdot \frac{p(x,y)}{p_Y(y)} \log \frac{p_X(x)}{p(x,y)} \\
&= \sum_y p_Y(y) \sum_x \frac{p(x,y)}{p_Y(y)} \log \frac{p_X(x)}{p(x,y)} \\
&\leq \sum_y p_Y(y) \log \sum_x \frac{p(x,y)}{p_Y(y)} \frac{p_X(x)}{p(x,y)} \\
&= \sum_y p_Y(y) \log \frac{1}{p_Y(y)} = H(Y).
\end{aligned}
$$

$H(Y|X) \leq H(Y)$ **cont.**

- Assume X and Y are independent (i.e., $p(x, y) = p_X(x) \cdot p_Y(y)$ for any x, y)

$\implies$ $p_{Y|X}(y|x) = p_Y(y)$ for any x, y

$\implies$ $H(Y|X) = H(Y)$

- Is the converse also true: $H(Y|X) = H(Y)$ implies X and Y are independent?

  Yes, since log is strictly concave in the range. Equality happens iff all t_i are the same,

- which happens iff $p(x, y) = p_X(x)p_Y(y)$ for all x, y

Other inequalities

- $H(X), H(Y) \leq H(X, Y) \leq H(X) + H(Y)$.

  Follows from $H(X, Y) = H(X) + H(Y|X)$.

  - Left inequality since $H(Y|X)$ is non negative.
  - Right inequality since $H(Y|X) \leq H(Y)$.

- $H(X, Y|Z) = H(X|Z) + H(Y|X, Z)$ (by chain rule)

- $H(X|Y, Z) \leq H(X|Y)$

  Proof:
  $$
  \begin{aligned}
  H(X|Y, Z) &= \mathop{\mathrm{E}}_{(z,y) \leftarrow (Z,Y)} H(X|_{(Y,Z)=(z,y)}) \\
  &= \mathop{\mathrm{E}}_{y \leftarrow Y} \mathop{\mathrm{E}}_{z \leftarrow Z|_{Y=y}} H(X|_{(Y,Z)=(z,y)}) \\
  &= \mathop{\mathrm{E}}_{y \leftarrow Y} \mathop{\mathrm{E}}_{z \leftarrow Z|_{Y=y}} H((X|_{Y=y})|_{Z=z}) \\
  &= \mathop{\mathrm{E}}_{y \leftarrow Y} H(X|_{Y=y}|Z|_{Y=y}) \\
  &\leq \mathop{\mathrm{E}}_{y \leftarrow Y} H(X|_{Y=y}) \\
  &= H(X|Y).
  \end{aligned}
  $$

Chain rule (for the entropy function), general case

Claim 2

For rvs $X_1, \ldots, X_k$, it holds that
$H(X_1, \ldots, X_k) = H(X_i) + H(X_2|X_1) + \ldots + H(X_k|X_1, \ldots, X_{k-1})$.

Proof: ?

- ▶ Extremely useful property!
- ▶ Analogously to the two variables case, it also holds that:
- ▶ $H(X_i) \leq H(X_1, \ldots, X_k) \leq \sum_i H(X_i)$
- ▶ $H(X_1, \ldots, X_K|Y) \leq \sum_i H(X_i|Y)$

Examples

- ▶ (from last class) Let $X_1, \ldots, X_n$ be Boolean iid with $X_i \sim (\frac{1}{3}, \frac{2}{3})$. Compute $H(X_1, \ldots, X_n)$
- ▶ As above, but X_n is set to $\bigoplus_{1 \le i \le n-1} X_i$?
  - ▶ Via chain rule?
  - ▶ Via mapping?

Applications

- Let $X_1, \ldots, X_n$ be Boolean iids with $X_i \sim (p, 1-p)$ and let $X = X_1, \ldots, X_n$. Let f be such that $\Pr[f(X) = z] = \Pr[f(X) = z']$, for every $k \in \mathbb{N}$ and $z, z' \in \{0, 1\}^k$. Let $K = |f(X)|$.

  Prove that $\mathsf{E}\, K \leq n \cdot h(p)$.

- $$\begin{aligned}
n \cdot h(p) &= H(X_1, \ldots, X_n) \\
&\geq H(f(X), K) \\
&= H(K) + H(f(X) \mid K) \\
&= H(K) + \mathsf{E}\, K \\
&\geq \mathsf{E}\, K
\end{aligned}$$

- Interpretation
- Upper bounds

Applications cont.

▶ How many comparisons it takes to sort *n* elements?

Let S be a sorter for *n* elements algorithm making *t* comparisons.

What can we say about *t*?

▶ Let X be a uniform random permutation of $[n]$ and let $Y_1, \ldots, Y_t$ be the answers S gets when sorting X.

▶ X is determined by $Y_1, \ldots, Y_t$.

Namely, $X = f(Y_1, \ldots, Y_t)$ for some function f.

▶ $H(X) = \log n!$

▶
$$
\begin{aligned}
H(X) &= H(f(Y_1, \ldots, Y_t)) \\
&\leq H(Y_1, \ldots, Y_t) \\
&\leq \sum_i H(Y_i) \\
&\leq t
\end{aligned}
$$

$\implies$ $t \geq \log n! = \Theta(n \log n)$

Concavity of entropy function

Let $p = (p_1, \ldots, p_n)$ and $q = (q_1, \ldots, q_n)$ be two distributions, and for $\lambda \in [0, 1]$ consider the distribution $\tau_\lambda = \lambda p + (1 - \lambda)q$.
(i.e., $\tau_\lambda = (\lambda p_1 + (1 - \lambda)q_1, \ldots, \lambda p_n + (1 - \lambda)q_n)$).

Claim 3

$H(\tau_\lambda) \geq \lambda H(p) + (1 - \lambda)H(q)$

Proof:

- Let Y over $\{0, 1\}$ be 0 wp λ
- Let X be distributed according to p if $Y = 0$ and according to q otherwise.
- $H(\tau_\lambda) = H(X) \geq H(X \mid Y) = \lambda H(p) + (1 - \lambda)H(q)$

We are now certain that we drew the graph of the (two-dimensional) entropy function right...

Part II

Mutual Information

Mutual information

- $I(X;Y)$ — the "information" that X gives on Y

-
$$\begin{aligned}
I(X;Y) &:= H(Y) - H(Y|X) \\
&= H(Y) - (H(X,Y) - H(X)) \\
&= H(X) + H(Y) - H(X,Y) \\
&= H(X) - H(X|Y) \\
&= I(Y;X).
\end{aligned}$$

- The mutual information that X gives about Y equals the mutual information that Y gives about X.

- $I(X;Y) \geq 0$.   When 0?

- $I(X;X) = H(X)$

- $I(X;f(X)) = H(f(X))$ (and smaller than $H(X)$ if f is non-injective)

- $I(X;Y,Z) \geq I(X;Y), I(X;Z)$ (since $H(X \mid Y,Z) \leq H(X \mid Y), H(X \mid Z)$)

- $I(X;Y|Z) := H(Y|Z) - H(Y|X,Z)$ ≥ 0

- $I(X;Y|Z) = I(Y;X|Z)$ (since $I(X';Y') = I(Y';X')$)

Numerical example

▶ Example

x\\$^Y$	0	1
0	$\frac{1}{4}$	$\frac{1}{4}$
1	$\frac{1}{2}$	0

$$
\begin{aligned}
I(X;Y) &= H(X) - H(X|Y) \\
&= 1 - \frac{3}{4} \cdot h(\frac{1}{3}) \\
&= I(Y;X) \\
&= H(Y) - H(Y|X) \\
&= h(\frac{1}{4}) - \frac{1}{2}h(\frac{1}{2})
\end{aligned}
$$

Chain rule for mutual information

Claim 4 (Chain rule for mutual information)

For rvs $X_1, \ldots, X_k, Y$, it holds that
$I(X_1, \ldots, X_k; Y) = I(X_1; Y) + I(X_2; Y|X_1) + \ldots + I(X_k; Y|X_1, \ldots, X_{k-1})$.

Proof: ? HW

Examples

- Let $X_1, \ldots, X_{n-1}$ be iid uniform bits (i.e., $X_i \sim (\frac{1}{2}, \frac{1}{2})$), and let $X_n = \bigoplus_{i \in [n-1]} X_i$. Compute $I(X_1, \ldots, X_{n-1}; X_n)$.
  - Directly,
    $I(X_1, \ldots, X_{n-1}; X_n) = H(X_n) - I(X_n | X_1, \ldots, X_{n-1}) = 1 - 0 = 1$
  - Using chain rule,

    $$I(X_1, \ldots, X_{n-1}; X_n)$$
    $$= I(X_1; X_n) + I(X_2; X_n | X_1) + \ldots + I(X_{n-1}; X_n | X_1, \ldots, X_{n-2})$$
    $$= 0 + 0 + \ldots + 1 = 1.$$

- Let T and F be the top and front side, respectively, of a 6-sided fair dice. Compute $I(T; F)$.

  $$I(T; F) = H(T) - H(T|F)$$
  $$= \log 6 - \log 4$$
  $$= \log 3 - 1.$$

Part III

Data Processing

Data processing inequality

> **Definition 5 (Markov Chain)**
>
> Rvs $(X, Y, Z) \sim p$ form a Markov chain, denoted $X \to Y \to Z$, if
> $p(x, y, z) = p_X(x) \cdot p_{Y|X}(y|x) \cdot p_{Z|Y}(z|y)$, for all x, y, z.

Example: random walk on graph.

> **Claim 6**
>
> If $X \to Y \to Z$, then $I(X; Y) \geq I(X; Z)$.

- By Chain rule, $I(X; Y, Z) = I(X; Z) + I(X; Y|Z) = I(X; Y) + I(X; Z|Y)$.
- $I(X; Z|Y) = 0$
    - $p_{Z|Y=y} \equiv p_{Z|Y=y, X=x}$ for any x, y
    -
        $$I(X; Z|Y) = H(Z|Y) - H(Z|Y, X)$$
        $$= \operatorname*{E}_{y \leftarrow Y} H(p_{Z|Y=y}) - \operatorname*{E}_{(x,y) \leftarrow (Y,X)} H(p_{Z|Y=y, X=x})$$
        $$= \operatorname*{E}_{y \leftarrow Y} H(p_{Z|Y=y}) - \operatorname*{E}_{y \leftarrow Y} H(p_{Z|Y=y}) = 0.$$
- Since $I(X; Y|Z) \geq 0$, we conclude $I(X; Y) \geq I(X; Z)$. $\square$

Fano's Inequality

▶ How well can we guess X from Y?

▶ Could with no error if $H(X|Y) = 0$. What if $H(X|Y)$ is small?

Theorem 7 (Fano's inequality)

For any rvs X and Y, and any (even random) g, it holds that

$$h(P_e) + P_e \log |\mathcal{X}| \geq H(X|\hat{X}) \geq H(X|Y)$$

for $\hat{X} = g(Y)$ and $P_e = \Pr\left[\hat{X} \neq X\right]$.

▶ Note that $P_e = 0$ implies that $H(X|Y) = 0$

▶ The inequality can be weakened to $1 + P_e \log |\mathcal{X}| \geq H(X|Y)$,

▶ Alternatively, to $P_e \geq \frac{H(X|Y)-1}{\log|\mathcal{X}|}$

▶ Intuition for $\propto \frac{1}{\log|\mathcal{X}|}$

▶ We call $\hat{X}$ an estimator for X (from Y).

Proving Fano's inequality

Let X and Y be rvs, let $\hat{X} = g(Y)$ and $P_e = \Pr\left[\hat{X} \neq X\right]$.

- Let $D = \begin{cases} 1, & \hat{X} \neq X \\ 0, & \hat{X} = X. \end{cases}$

$$H(D, X | \hat{X}) = H(X | \hat{X}) + \underbrace{H(D | X, \hat{X})}_{=0}$$

$$= \underbrace{H(D | \hat{X})}_{\leq H(D) = h(P_e)} + \underbrace{H(X | D, \hat{X})}_{\leq P_e \log |\mathcal{X}| (?)}$$

- It follows that $h(P_e) + P_e \log |\mathcal{X}| \geq H(X | \hat{X})$
- Since $X \to Y \to \hat{X}$, it holds that $I(X; Y) \geq I(X; \hat{X})$
  $\implies H(X | \hat{X}) \geq H(X | Y)$
